1.0 INTRODUCTION

Armed with the widely supported 2009 Salt Lake Countywide Water Quality Stewardship Plan (WaQSP), regulatory and municipal authorities in Salt Lake County seek to work collaboratively to monitor and improve watershed and stream health. After examining the current conditions, numerous water quality and watershed improvement recommendations were made in the 2009 WaQSP. However, written recommendations and well laid plans are only as good as the implementation efforts that result. With the completion of the WaQSP, Salt Lake County and its partners now enter the most challenging and rewarding phase of watershed management—implementation. A key challenge in the implementation phase is to measure the success and/or failure of implementation efforts. Therefore, to inform future planning decisions, and to assure a successful, iterative, planning and implementation process, Salt Lake County developed a monitoring tool for the WaQSP known as the Stream Function Index (SFI). The SFI was developed in 2006 with the assistance of several environmental consulting firms. The primary consultant on this effort was Cirrus Ecological, based in Logan, UT.

It is anticipated that SFI data will be collected along with each update of the WaQSP that will occur every six years. It is also anticipated that reports, such as this one, will be written for each municipal government at that same frequency. Successful implementation of WaQSP recommendations should lead to improved SFI scores. However, if BMPs do not lead to improved SFI scores, they will be re-examined for effectiveness in the local environment.

1.1 COMPONENTS OF THE STREAM FUNCTION INDEX (SFI) AND ECOSYSTEM HEALTH INDEX (EHI)

Streams and rivers, although single components of the larger watershed, may serve as indicators of overall watershed health. To maximize resources and time, Salt Lake County decided to focus on monitoring stream and river corridors to indicate overall watershed function. However, a broader examination of watershed function may be accomplished in the future with increased funds and staff. For the purposes of this document, data collected in stream and river corridors are used to indicate watershed function.

To monitor stream and river health, the SFI measures physical, chemical, biological, and social functions of stream and river corridors in Salt Lake County. The four watershed functions that are examined in the SFI include: habitat (aquatic and terrestrial), hydraulics (flood conveyance and stream stability), water quality and social (recreation and aesthetics). Metrics used to determine scores for each of the four watershed functions are included in Table 1. Recreation and aesthetics monitoring is included in the SFI to indicate the degree to which stream and river corridors provide appropriate, or resource compatible, recreation and aesthetic opportunities. However, recreational facilities may, if incompatible with the resource, detrimentally effect stream ecology.

In order to examine ecological health independent of social function, Salt Lake County created an Ecological Health Index (EHI). The EHI is a sub-component of the SFI that includes habitat, hydraulics, and water quality evaluations. The EHI may be compared with the SFI to determine possible effects of social (i.e. recreational and aesthetic) functions on stream ecology.

See the “Stream Function Index Main Report” Appendices for the complete SFI Methodology Report.

1.2 DATA COLLECTION

The majority of 2009 SFI numbers were based on data gathered between 2007 and 2008. However, water quality data spans a greater time period (2001 to 2008). In future SFI updates, it is anticipated that water quality data collected between updates will be used to assess stream health. Although previous stream stability and fish...
Salt Lake County—Stream Function Index (SFI)
West Jordan City

Habitat assessments were conducted on a few streams and the Jordan River in the mid 1980’s, the 2009 SFI represents the first comprehensive assessment of all major waterways in Salt Lake County. Therefore, this dataset is considered a baseline.

The SFI is intended to give watershed and stream managers an overview of current stream conditions. However, as improvement projects are identified, more detailed studies may be required to fully assess the condition of the stream.
Salt Lake County—Stream Function Index (SFI)
West Jordan City

2.0 WEST JORDAN CITY—INFORMATION

The City of West Jordan, located in the central portion of Salt Lake County, is a relatively old city (incorporated in 1941) and is home to approximately 138,390 residents. Contained within West Jordan’s boundaries are portions of three sub-watersheds: Bingham Creek, Barney’s Creek and the Jordan River Corridor. Additionally, sections of Barney’s Creek, Bingham Creek, and the Jordan River are found within the City boundaries. This report summarizes the health of the river and stream sections within the City of West Jordan and provides guidance for future water quality improvement and watershed preservation efforts. West Jordan City will also receive a copy of the 2009 WaQSP Addendum Stream Function Index Main Report, and will receive electronic files of the report and Geographic Information System (GIS) shapefiles depicting information collected as part of the SFI.

2.1 WATER QUALITY STRESSORS IN WEST JORDAN CITY

Although the SFI is a measure of stream corridor health, it is imperative that water quality and watershed health be approached comprehensively. Therefore, this section is provided to review water quality stressors identified in the 2009 WaQSP for the sub-watersheds in West Jordan City.

As part of the 2009 WaQSP, a computer-based GIS analysis was conducted for each of the 27 sub-watersheds in Salt Lake County to determine existing and potential future water quality stressors. In Chapter 5 of the WaQSP document, these water quality stressors are outlined and Best Management Practices (BMPs) recommended to address potential concerns. Below are examples of water quality stressors and associated BMPs. To determine water quality stressors identified in sub-watersheds that intersect West Jordan City boundaries, please consult the 2009 WaQSP.

Water quality stressors may include:
- Stream channel modification
- Lack of developed recreation
- Stream flow diversions
- Loss of open space
- High number of Industrial Stormwater Discharge Permits
- Floodplain encroachment
- Densification of residential land use
- Urban development and redevelopment pressures

Examples of Management Practices (BMPs) to address potential water quality stressors include:
- Stream channel modification
- Lack of developed recreation

West Jordan City - 4

2009

Salt Lake County—Stream Function Index (SFI)
West Jordan City

- Stream flow diversions
- Loss of open space
- High number of Industrial Stormwater Discharge Permits
- Floodplain encroachment
- Densification of residential land use
- Urban development and redevelopment pressures
- Bioengineered bank stabilization
- Grade control structures
- Channel restoration/enhancement
- Streambank revegetation
- Diversion structures modification
- Canal water diversion
- Leadership in Energy and Environmental Design criteria
- Minimum flow protection
- Water rights acquisition
- Identify community recreation needs and opportunities
- Wetlands restoration/enhancement
- Manufactured treatment systems
- Participate in new and/or existing planning efforts
- Floodplain re-establishment
- Trash racks
- Land acquisition for preservation
- Volunteer programs
- Recreational facilities that are accessible and resource compatible.

Salt Lake County developed what is called the Stream Function Index (SFI). The SFI is a rapid assessment protocol that assesses stream habitat, hydraulics, water quality and social factors. Based on established methodology, the SFI measures 27 metrics to determine overall stream health. These metrics are categorized by watershed function (water quality, habitat, hydraulics, social/aesthetic) and can therefore be examined individually or by functional group.

The SFI is a tool to help identify the results of water quality stressors along main stream channels and the Jordan River. These areas are candidates for enhancement projects. The SFI provides the framework for a more detailed baseline and monitoring techniques that may be used on those projects. The first complete dataset was collected during the 2007 and 2008 field seasons and is considered the baseline. The SFI will be repeated every 6 years in conjunction with the Water Quality Stewardship Plan Update.

4.0 WATERSHED FUNCTION GROUPS

This section summarizes scores for the four watershed functions countywide and reviews data and scores within West Jordan City boundaries. Additional information on SFI methodology can be found in the SFI Main Report.

4.1 WATER QUALITY FUNCTIONAL GROUP SCORE

The SFI water quality functional group is comprised of seven metrics or measures: 303(d) list status, macroinvertebrates, Total Phosphorus, Temperature, Total Dissolved Solids (TDS), Dissolved Oxygen (DO), and Coliform (E. Coli). Based on 2009 SFI scores, the streams with the best water quality are concentrated in the upper regions of both the Wasatch and Oquirrh streams, with the notable exception of upper Little Cottonwood Creek (currently listed as water quality impaired by the State Division of Water Quality) for zinc. Additionally, sections of lower Emigration Creek and Red Butte Creek received high rankings for water quality. Notably, these scores are based entirely on data contained in the Environmental Protection Agency’s STORET database. Although this data represents a large portion of water quality data collected in Salt Lake County, it does not represent all data. However, it was decided that the SFI would rely on STORET data to assure
consistent methodologies and that certified water quality assurance (QA) and water quality control (QC) measures were taken.

In addition to noting areas of high, or good, water quality, it is important to note areas of low, or poor water quality. As can be seen from the Countywide data presented in Figure 1, segments with low water quality values include: upper and lower Jordan River, lower and upper Little Cottonwood Creek, lower Big Cottonwood Creek, and upper Emigration Creek. All of these segments scored as meeting water quality standards in <50% of samples taken. Many of these water quality concerns are currently being addressed through the State Division of Water Quality’s (DWQ) Total Maximum Daily Load (TMDL) program. TMDL studies are currently underway for the Jordan River, Upper Emigration Creek, and Upper Little Cottonwood Creek. Additionally, Lower Big and Little Cottonwood Creeks are listed as impaired on DWQ’s 303(d) list of impaired water bodies.

Water quality concerns in West Jordan City are focused on the Jordan River. Pollutants of concern include Total Dissolved Solids (TDS), and temperature. In order to address these concerns, it is recommended that West Jordan City actively participate in the Jordan River TMDL process by attending Jordan River Watershed Council (JRWC) meetings and reviewing documents that are published in conjunction with the Jordan River TMDL.
4.2 HABITAT FUNCTIONAL GROUP SCORE

In the SFI, the habitat function was characterized by: pool/riffle ratio, fish passage, habitat structure, flow diversion, riparian width, and riparian density. Of note, stream channel habitat metrics were only assessed for streams that have been identified, by the State Division of Wildlife Resources (DWR) as supporting fish habitat. Flow diversion and riparian metrics were assessed for all streams.

Similar to the Water Quality Functional Group Score, streams with the best, or highest scores, are concentrated in the upper regions of both the Wasatch and Oquirrh mountains. However, in contrast to water quality, not all sections of upper Oquirrh Mountain streams rank high for habitat. Of note, Copper Creek and Rose Creek both scored <60% for overall habitat function. Other areas of particular habitat concern include lower Big and Little Cottonwood Creeks and the section of Butterfield Creek upstream from its confluence with Midas Creek.

As can be seen from Figure 2, West Jordan City contains sections of Barneys Creek that scored between 60 and 69.9 for overall habitat function. For overall habitat, the Jordan River in West Jordan scored between 50 and 59.9 and Bingham Creek scored between 10 and 19.

Recommendations to improve habitat function in West Jordan City will be further explored in the following sections that examine specific habitat concerns.
4.2.1 Pool/Riffle Ratio in West Jordan City

An important component of stream habitat function is the ratio between pools and riffles. For the SFI, the number of pools and riffles were counted for each stream reach. Pools were defined as mid-channel areas with low velocity that were at least 1 foot deep. Riffles were defined as mid-channel shallow turbulent areas of higher velocity. The number of pools was compared to the expected number for the given stream type. (see SFI Main Report for an explanation of stream type.) Subsequently, the pool/riffle ratio was determined. As with other fish habitat metrics, a score of “Not Applicable” (N/A) indicates that the stream does not support a fishery.

As indicated in Figure 3, the sections of Barney’s and Bingham Creek within West Jordan City were not scored for pool/riffle ratio because they are not designated fisheries by the State Division of Wildlife Resources (DWR). The portion of the Jordan River within West Jordan City scored between 1 and 50.

Recommended actions to improve pool/riffle ratio in West Jordan City include: participating in river restoration projects that incorporate habitat enhancement measures to improve pool/riffle ratio, and participating in discussions regarding opportunities to accommodate flood control, water rights, recreation, and instream habitat needs.
4.2.2 Water Depth in West Jordan City

In Salt Lake County, many streams have experienced altered or reduced stream flow or may naturally have minimal stream flow. In order to assess the extent to which streams have sufficient water depth to support aquatic habitat, Salt Lake County staff measured stream depth at representative locations within each stream reach during late summer low flow. Targets for this metric were set based on minimum depth requirements for trout and native sucker species established by the Utah Division of Wildlife Resources (DWR).

As can be seen in Figure 4, the section of the Jordan River within West Jordan City boundaries ranked high for water depth (100). The tributaries were again not scored because they are not classified as fisheries by the State DWR. Although the flow through this section of the Jordan River is highly altered, the remaining water depth appears sufficient to support fish habitat. Therefore, no immediate action is required for this metric; however, it is recommended that West Jordan City monitor any water right activities that may alter water depth within this section of the Jordan River and seek to sustain existing water depths.

Figure 4. Habitat Function—Water Depth in West Jordan City
4.2.3 Fish Passage in West Jordan City

For the purposes of the SFI, fish passage was scored based on the distance between barriers to fish passage. Barriers were tallied for each stream reach and analyzed for overall function during late summer low flow. Barrier criteria included height of barrier, depth of plunge pool, water depth, and beaver dam density. The optimum value for this metric was to have at least 1/4 of a mile between barriers.

As can be seen from Figure 5, the section of the Jordan River within West Jordan City received a high score for fish passage (100). Therefore, no immediate action is recommended for this metric. However, it is recommended that West Jordan City closely monitor any future stream alterations that may occur in this section of the Jordan River to assure that fish passage is sufficiently accommodated in any new structure. As with pool/riffle ratio and water depth, Barney’s and Bingham Creeks were not scored for fish passage because they are not classified as fisheries by the State DWR.
4.2.4 Habitat Structure in West Jordan City

For the purposes of the SFI, habitat structures are defined as instream natural, or man-made, objects that provide cover, resting, and feeding resources for fish species. To measure the function of habitat structures, the number of embedded logs, rootwads, boulders, undercut banks, beaver dams, and man-made structures were tallied for each reach. Targets were set based on the number of habitat structures anticipated to occur in specific stream types.

As can be seen from Figure 6, the majority of the Jordan River section within West Jordan City boundaries scored 0 for habitat structure. Additionally, a smaller section in the southern portion of the city scored between 26 and 50 for this metric. Therefore, enhancement efforts are encouraged to improve habitat structure in West Jordan City. The tributaries were not scored for instream habitat metrics because they are not designated as fisheries by DWR.

Recommended actions to improve habitat structure resources in West Jordan City include: participating in river restoration projects that incorporate habitat enhancement measures, participate in discussions regarding opportunities to accommodate flood control, water rights, recreation, and habitat needs. As with many metrics, habitat structures are essential to stream function, but need to be balanced with other stream functions.
4.2.5 Flow Diversion in West Jordan City

In the arid environment of Salt Lake County, many streams have been greatly impacted due to altered surface and groundwater flows. To include potential effects on habitat in the SFI, Salt Lake County developed a flow diversion metric. The flow diversion metric measured the degree to which natural surface stream flows have been reduced or interrupted. This metric includes both the amount of time over a year and the length of stream that is maintaining natural flows. The target for this metric was set at 100%, i.e. a natural flow for 100% of the year.

As can be seen in Figure 7, the majority of Bingham Creek and Jordan River within West Jordan City’s boundaries scored extremely poorly for flow diversion (0). Barneys Creek, however, scored high for this metric (100).

To improve habitat and address flow diversions, it is recommended that West Jordan City participate in any discussions to examine flow management of the Jordan River. Of note, the 2009 WaQSP document calls for a comprehensive review of Jordan River flow management. Additionally, it is recommended that West Jordan City work with local water right holders and Salt Lake County Flood Control to identify opportunities to improve instream flows in Barneys and Bingham Creeks.
4.2.6 Riparian Width in West Jordan City

The SFI also examined habitat beyond the stream channel with Riparian habitat metrics. The first metric examined was the width of riparian corridors. For the purposes of the SFI, riparian width was measured as the continuous and contiguous areas of uninterrupted vegetation growth along streams. The target riparian width was established by Salt Lake County to be 100 feet, i.e. ideally, all streams/river in the County would be bordered on both sides by 100 feet of uninterrupted vegetative growth. The actual amount of riparian vegetation was then compared with the target.

As can be seen in Figure 8, a large portion of the Jordan River within West Jordan City boundaries scored between 26 and 50 for riparian width. However, a smaller section scored higher (between 51 and 75). Generally, the tributaries had lower scores (between 0 and 25) for riparian width.

To improve riparian habitat function of the streams and river in West Jordan City, it is recommended that the City pass a land use ordinance to limit development within 100 feet of streams and river (this may also be included in development codes), and again work with other authorities to promote vegetative growth along the streams and river. Of note, such a land use ordinance was also recommendation in the 2009 WaQSP document.
4.2.7 Riparian Density in West Jordan City

In addition to riparian width, the density of riparian vegetation is a strong indicator of overall stream health. This metric scores the percent coverage of the canopy, middle story, and understory to determine overall riparian density. As opposed to examining plant species, this metric assumes that the highest functioning riparian areas will have at least 80% coverage at all levels of the canopy.

As can be seen in Figure 9, most of the section of Jordan River within West Jordan City boundaries scored high for this metric (between 76 and 100). However, a smaller section of the Jordan River within West Jordan City scored lower (between 26 and 75). The majority of the tributaries scored between 1 and 50.

To improve stream function and augment habitat resources, it is recommended that West Jordan City participate with other State and local authorities to: sponsor river/stream restoration efforts that incorporate robust re-vegetation and irrigation efforts, notify residents of tree planting efforts and encourage their participation. In addition to working with other authorities and nonprofit organizations, it is recommended that West Jordan City actively manage recreation areas to encourage riparian vegetation growth.
4.3 HYDRAULICS FUNCTIONAL GROUP SCORE

The third watershed function examined for the purposes of the SFI was hydraulics function. This functional group is comprised of four metrics: floodplain development, floodplain connectivity, bank stability, and hydraulic alteration.

As can be seen in Figure 10, the majority of streams in Salt Lake County scored > 50 for the hydraulic function; however, an appropriate target for this functional group is closer to 75. Countywide, the streams with low hydraulic function scores were concentrated in the lower sections of the Wasatch Mountain streams. Namely, City Creek, Red Butte Creek, Emigration Creek, and Parley’s Creek showed low hydraulics function. This may be due to the highly developed nature of these stream and the extensive culverts on each of them.

Barneys and Bingham Creeks within West Jordan City boundaries scored relatively high for this functional group (between 70 and 79.9). The Jordan River scored lower (between 60 and 69.9) for overall hydraulic function. The following information is provided to review hydraulic function metrics within West Jordan City and identify opportunities to improve stream function by addressing concerns.
4.3.1 Floodplain Development in West Jordan City
The floodplain development metric evaluates the percent of impervious surface within the 100 year floodplain as defined by the FEMA Flood Insurance Program. For the purposes of the SFI, the target was that 100% of the floodplain be pervious, or free from development that would limit groundwater infiltration.

As can be seen in Figure 11, the majority of streams within West Jordan City scored >76 for floodplain development. The Jordan River scored between 76 and 99 for this metric.

The relative lack of impervious areas along the streams and river in West Jordan City is a great opportunity. The challenge will be to encourage appropriate development while limiting inappropriate development in these established floodplains. This could be done either through development codes or land use ordinances. Of note, the 2009 WaQSP recommends that all cities within Salt Lake County develop and adopt ordinances that will both limit impervious surface and development along stream and river corridors.
4.3.2 Floodplain Connectivity in West Jordan City

The floodplain connectivity metric is essentially a measure of stream entrenchment (or eroded streambed). Entrenchment disconnects the stream from its historic floodplain, lowers the water table, and increases the intensity of flood events. For the purposes of the SFI, floodplain connectivity was measured and scored against targets established by stream type (see SFI Main Report.) Any score falling within the appropriate entrenchment range for a stream type was given a score of 100. If the entrenchment ratio was outside the appropriate range, the reach was given a score of 0.

As can be seen in Figure 12, the middle section of the Jordan River within West Jordan City boundaries scored low for floodplain connectivity (0). However, the upper and lower sections of the Jordan River within the City boundaries had entrenchment ratios within the target range (100). The tributaries within West Jordan City had variable entrenchment scores—each of which will need to be examined individually for opportunities to improve floodplain connectivity. It is therefore recommended that West Jordan City partner with other authorities to conduct stream/river restoration efforts that may reconnect the stream with its historic floodplain. Salt Lake County has successfully used an emergent bench design for similar sections of the Jordan River (see Figure 18 on page 22).
4.3.3 Hydraulic Alteration in West Jordan City

Although bank stability is key to the hydraulics function of an urban stream, artificial bank configurations that reduce riparian and floodplain areas and the types of artificial materials used may cause stability and habitat problems. For the SFI, hydraulic alteration was evaluated as the percent of culverts and man-made bank stabilization structures and built with materials such as concrete riprap or gabion baskets within a reach. The percent was based on visual observation by field personnel and computer-aided mapping of culverts.

As can be seen in Figure 13, the section of the Jordan River that runs adjacent to West Jordan City scored high for hydraulic alteration (100). However, the tributaries in the City had lower scores with large sections scoring between 1 and 25 for this metric. Therefore, it is recommended that West Jordan City focus enhancement efforts on Barneys and Bingham Creek.

It is recommended that when upgrading bank stabilization structures or when new bank stabilization projects are necessary, West Jordan City partners with Salt Lake County Flood Control Division and State agencies to employ ecosystem restoration techniques. Additionally, it is recommended that West Jordan City work to protect the integrity of sections that scored 76 and higher. This may be done by closely monitoring requests for stream alterations in this area.
4.3.4 Bank Stability in West Jordan City

In addition to measuring the condition and frequency of man-made stability structures in Salt Lake County’s streams and river, an established bank stability method was also employed to characterize overall stream stability.

The Pfankuch Stream Stability Evaluation protocol—developed for the U.S. Forest Service—was slightly modified for use on the urban streams of Salt Lake County. Although the Pfankuch rating is only one of the metrics contained in the SFI, it, in itself, examines 18 stream characteristics. This metric therefore contains abundant information that may be used in stream restoration and enhancement projects. “Hot spots”, or actively eroding sites, were also identified and mapped. Although the presence of a hot spot did not contribute directly to the score, they give an indication of where to perhaps prioritize bank stabilization projects.

As can be seen in Figure 14, the majority of the tributaries in West Jordan City scored “Good” for bank stability; however, the section of the Jordan River within the city boundaries scored “Fair” for this metric. Additionally, numerous “hot spots” were observed in Barneys Creek, Bingham Creek and the Jordan River that are actively eroding.

In order to improve bank stability and enhance hydraulic function in West Jordan City, it is recommended that the City work with local land owners, Salt Lake County Flood Control, and other regulatory and nonprofit organizations to identify opportunities for stream enhancement through restoration efforts. This data may guide the City in its efforts.
4.4 SOCIAL FUNCTIONAL GROUP SCORE

Social watershed function was measured by examining recreational facilities: management, aesthetics, location, Americans with Disabilities Act (ADA) compatibility, restroom facilities, trail connectivity, and resource compatibility.

Social function is probably the most difficult function to measure because there is a broad range of preferences by recreationists for different types of facilities. Therefore, the SFI focused on assessing the availability of all types of recreation facilities along the waterways, the minimum requirements for a positive user experience, and impact that the use of those facilities may have on the stream ecosystem. Although recreation may have detrimental impacts on stream and river corridors, it is the opinion of Salt Lake County staff that the best way to promote stewardship of local resources is to provide appropriate facilities and access.

As can be seen in Figure 15, the section of the Jordan River flowing through West Jordan City scored between 60 and 69.9 for overall social function; whereas, the tributaries in West Jordan scored lower (between 40 and 59.9). In order to encourage appropriate access to the streams and river in West Jordan, the City is encouraged to work with local property owners to identify opportunities for enhanced recreational access to the streams.
In order to determine the physical, chemical, and biological health of streams in Salt Lake County, the County has developed an Ecosystem Health Index (EHI) score. This score is meant to reflect the ecological health of the stream. Although the County’s position is to promote responsible and appropriate recreational access along the stream corridors, it is also understood that recreational activities may counteract ecological function. Therefore, it is important to examine the combined EHI score outside of the overall Stream Function Index (SFI) score which includes the Social Function.

As can be seen in Figure 16, the Jordan River scored between 60 and 69.9 within West Jordan City boundaries. Barneys Creek scored higher (between 70 and 79.9), Bingham Creek scored between 50 and 59.9. In review of the EHI components, it appears that these scores are largely driven by habitat scores. However, because the tributaries within West Jordan are not designated as fisheries, these scores are strongly influenced by riparian habitat and flow metrics. To address these concerns, it is recommended that West Jordan City partner with adjacent cities and other agencies to identify opportunities for habitat enhancement and establish zoning ordinances and/or regulations that will limit development along their streams and river.

Figure 16. Ecosystem Health Index (EHI) Final Score 2009
To include social/recreational functions in the overall SFI score, Salt Lake County combined the EHI with social scores.

As can be seen in Figure 17, the Jordan River and Barneys Creek had SFI scores between 60 and 69.9 within West Jordan City boundaries. Bingham Creek scored lower (between 50 and 59.9). In review of the SFI components, it appears that these scores are driven by water quality, habitat and social function scores.

To address these concerns, it is recommended that West Jordan City partner with adjacent cities and other agencies to complete and implement the Jordan River TMDL in an efficient and timely manner. It is also recommended that West Jordan City seek partners and explore stream/river restoration efforts. Additionally, it is recommended that West Jordan City establish zoning ordinances and/or regulations that will limit development along their streams and river. It is also recommended that West Jordan City make efforts to include recreational facilities in development along the streams and river within the City's boundaries.
7.0 IMPLEMENTATION

Because many of the recommendations included in this document suggest stream/river restoration efforts, this section is written to provide some general guidelines/suggestions with such projects.

7.1 SITE IDENTIFICATION

Salt Lake County encourages local cities to consult the data collected as part of the SFI effort to identify appropriate restoration sites. In addition to the GIS data that each city will be provided, Salt Lake County staff are available for consultation and assistance with grant application efforts.

7.2 PLAN DEVELOPMENT

Salt Lake County has used an “Emergent Bench” design for restoration projects along the Jordan River (Figure 18). This design is appropriate for reaches with large easements/access. If easements are not available, other designs may need to be developed. Currently, Salt Lake County is working to develop ideas for entrenched, urban reaches.

7.3 FUNDING

As with most municipal functions, a major hurdle to stream/river restoration projects is funding. Some municipalities have elected to use stormwater utility fees or bond efforts to fund such projects. However, the majority of projects that have been completed in Salt Lake County have relied heavily on Federal grants. Fortunately, numerous Federal grants are available to support stream restoration efforts. However, the cost of site identification and plan development usually fall to the sponsoring agency.

Although application deadlines and typical amounts awarded vary greatly, there are some common characteristics of successful grant applications:

---

Figure 18. Diagram of Emergent Bench design used along the Jordan River
A clear, precise workplan
- Demonstrated involvement of many partners
- Inclusion of a monitoring effort
- Strong financial match

A list of some grants that may be appropriate are provided in Table 3, Grants for Stream and River Restoration Projects.

7.4 PLAN IMPLEMENTATION

With robust planning, established partnerships, and sufficient funding, stream and river restoration efforts may be highly successful. However, some pitfalls do exist. Things to be aware of during a stream restoration effort:

- Flow diversions may occur unexpectedly. Please assure that all permits (namely stream alteration and flood control permits) have been acquired and appropriate entities notified to avoid the unexpected destruction of restoration work.

- Order your plant and rock material early as many of these materials are in high demand.

- Notify the public. Although stream and river restoration efforts are a great benefit to the local stream health, the process of restoration may at times appear destructive. Post notices explaining the project in order to prevent public misunderstanding.

- Allow enough time. As with most projects, stream and river restoration projects may take longer than expected. Be sure to plan for unexpected delays in your scheduling.

- We’re not the only ones that love trees. In many of the restoration efforts that Salt Lake County has overseen, beaver activity has been highly destructive. Be sure to consult local experts to prevent the destruction of your newly planted trees.

7.5 POST-CONSTRUCTION

One of the most important components of a successful stream or river restoration project is the long-term maintenance of the restoration site. Especially in the arid Salt Lake Valley, be sure to plan for irrigation of planted vegetation, and weed control to assure that the monies spent on the restoration project are used to their fullest extent; budgeting for a two-year establishment period is ideal.

Example of before (above) and after (right) river restoration project completed in 2009 using Emergent Bench model along the Jordan River. This site in Riverton will be irrigated for 2 years to establish vegetation.
