Field Guide for Managing Russian Olive in the Southwest
The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or part of an individual’s income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA’s TARGET Center at (202) 720-2600 (voice and TTY). To file a complaint of discrimination, write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, SW, Washington, DC 20250-9410 or call (800) 795-3272 (voice) or (202) 720-6382 (TTY). USDA is an equal opportunity provider and employer.
Russian olive (*Elaeagnus angustifolia* L.)
Oleaster family (Elaeagnaceae)

Russian olive is widespread throughout the United States as a tree and is listed as a noxious weed in New Mexico. This field guide serves as the U.S. Forest Service’s recommendations for management of Russian olive in forests, woodlands, and rangelands associated with its Southwestern Region. The Southwestern Region covers Arizona and New Mexico, which together have 11 national forests. The Region also includes four national grasslands located in northeastern New Mexico, western Oklahoma, and the Texas panhandle.

**Description**
Over the past century, Russian olive (synonyms: oleaster, wild olive, and silver berry) was widely planted throughout the United States as an ornamental and windbreak tree that has since escaped into natural areas. It is a hardy, fast-growing, deciduous tree that grows to about 30 feet in height. Russian olive is silvery in appearance and highly aromatic; its thorny branches are loosely arranged in a rounded shape.

**Growth Characteristics**
- Deciduous tree (10 to 40 feet tall) or long lived, multistemmed shrub.
- Trunk has a circumference of 4 to 20 inches; has dark, smooth, or sometimes shredded-looking bark.
- Branches are loosely arranged; reddish-brown with silvery scales; twigs are thorn tipped with silvery scales; 1- to 2-inch thorns.
- Alternate, simple, lance-shaped leaves, 0.8 to 4 inches long; upper surface is pale green with silvery, star-shaped hairs; lower leaf has dense, silvery-white scales.
- Roots can grow as deep as 40 feet; symbiotic nitrogen-fixing bacteria in roots allow Russian olive to grow on bare-mineral substrate.
- Fragrant, yellow flowers arranged in clusters; flowers May to July.
- Clusters of small, hard, olive-like, yellowish to reddish-brown fruits (drupes, 0.5 inch long) with a dusting of silver scales; fruit matures August to October.
- Reproduces primarily by seed, although sprouting from buds at the root crown and suckers from lateral roots also occur.
- Seeds are brown, oval shaped 0.25 to 0.5 inch long; seed produced after tree is 4 to 5 years old; seed viable for 3 years.

**Ecology**

**Impacts/threats**
Russian olive is problematic in the Southwest because it favors riparian communities and other moist environments. As populations increase, Russian olive crowds out desirable native riparian trees such as cottonwood and willow, thereby reducing flora and fauna species diversity. Because of its ability to colonize streambanks, Russian olive can alter the natural flooding regime and reduce availability of nutrients and moisture.

**Location**
Russian olive prefers areas where the water table is near the soil surface such as in riparian zones, flood plains, and valley bottoms. It commonly grows near water tanks, irrigation ditches, and springs; along roads, railways, and fence lines; and in subirrigated pastures and grasslands. It occurs from sea level to about 8,000 feet of elevation and is semishade tolerant.

**Spread**
Russian olive seed is relished by birds, and bird droppings with the seed contribute greatly to the tree’s spread. Coyotes, deer, and raccoons consume the fruit as do small mammals which value the seed as a food source as they widely carry and stockpile seed. The fruit floats and is easily transported and dispersed along waterways. Russian olive also grows and spreads from stump sprouts, stem cuttings, and root pieces, especially after parent trees have been cut.
**Invasive Features**

Russian olive tolerates a wide range of environmental conditions including high winds, flooding, drought, extreme temperatures (-50 °F to 115 °F), saline or alkaline soil conditions, and competition from other trees and shrubs. Russian olive can become the dominant species in areas after invasion due to its adaptability, aggressive reproduction, and rapid growth rate. It may form dense, monotypic stands that can impede establishment of willow and cottonwood seedlings.

**Management**

Russian olive is viewed by some people as a horticulturally desirable species, and the tree is still sold in nurseries. In the past, it was promoted by various agencies for conservation plantings in cropland environments. Some of these same agencies are now spending large sums of money to control it. While the popularity of using Russian olive as a drought-resistant planting option is not as common as it was in the past, public education is still needed to raise awareness of the tree’s invasive shortcomings.

It is extremely difficult to restore native plant communities in areas where Russian olive has become well established. The first priority in Russian olive management is to prevent establishment by monitoring for its first appearance. Small infestations on otherwise healthy sites should be treated early, and the goal should be to remove all trees. Control efforts must focus on the destruction of the root system. Treatments such as dozing, burning, and cutting can effectively eliminate aboveground growth but do little to control the root system and limit recruits. It may be impractical to eradicate Russian olive completely when growing in larger infestations, but trees should be controlled to the best extent possible. Russian olive management requires a long-time commitment that will likely take 3 or more consecutive years of treatment followed by 1 to 2 years of monitoring for regrowth. Strategies to contain and reduce Russian olive populations are best developed through long-term planning and integrated management.

The following actions should be considered when planning an overall management approach:

- Maintain healthy and diverse plant communities.
- Provide landowners with ideas for noninvasive alternatives to Russian olive for soil stabilization, windbreaks, and ornamental use.
- Limit disturbance and/or promptly revegetate disturbed areas with desirable riparian plant species, such as cottonwood and willow.
- Where possible, maintain or simulate seasonal flooding in riparian areas.
- Detect, report, and map known infestations. Keep annual records of reported infestations.
- Eradicate new populations of Russian olive as early as possible.
- Combine mechanical, cultural, and chemical methods for most effective Russian olive control.
- Implement monitoring and followup treatment plan for missed plants and seedlings.

Table 1 summarizes some management options for common situations involving Russian olive. Choice of which method(s) to use for Russian olive control will depend on a number of factors including the age, size, and density of trees. Site conditions (land use, accessibility, terrain, climate, other flora and fauna present, etc.) where the infestation occurs will greatly influence control decisions. Other considerations include treatment effectiveness, cost, and the number of years needed to achieve control. More than one control method may be needed for a particular site.

**Special Considerations**

Along with saltcedar (Tamarix spp.), Russian olive potentially serves as nesting habitat for the endangered southwestern willow flycatcher (*Empidonax traillii extimus*) which is protected under the Endangered Species Act of 1973. To avoid harm to this endangered species, information should be obtained from the U.S. Fish and Wildlife Service (Arizona, phone (602) 242-0210; New Mexico, phone...

</table>

* Choice of a particular management option must be in compliance with existing regulations for land resource.

(505) 248-6920) before implementing treatment of Russian olive stands of 0.25 acre or more in riparian or wetland areas within Arizona or New Mexico. A formal survey for flycatcher nesting habitat by a surveyor with a scientific permit may be required for a site with Russian olive prior to treatment if the nesting status of the site is undetermined. Within occupied or suitable flycatcher habitat, Russian olive treatment operations (including ground or aerial herbicide spraying) should not occur during the flycatcher nesting period of April 15 to August 30. When nesting habitat of the southwestern willow flycatcher is present, a no-treatment buffer of 0.25 mile is necessary around the nest(s). Migratory birds other than the flycatcher may also nest in Russian olive from April through August, and treatment of Russian olive during this period should be avoided if possible.
**Physical Control**

Physical methods to control Russian olive should focus on reducing seed production and preventing germination, mainly through removal or impairment of seed producing plants. Methods that stress and/or remove the root system should also be employed. These methods usually have to be followed up with repeated treatment of seedlings and root resprouts. Long-term effectiveness may be increased by applying herbicide after cutting (see the “Chemical Control” section).

**Manual Methods**

**Hand removal** – Small trees (< 3.5 inches diameter) may be hand grubbed with a shovel, hoe, or weed tool such as the Weed Wrench™ or Root Talon™.

**Mechanical Methods**

**Suppression of saplings by mowing** – Where sapling stems do not exceed 1 inch in diameter, use a tractor fitted with a brush mower to shear plants close to the ground surface. Gather and pile cut material for burning or shredding. Mowing will not kill Russian olive trees, and plants can become multistemmed and brushy if mowing is not repeated. Repeat mowing before saplings reach a diameter of 1 inch (likely annually). A wet-rotary blade with glyphosate may also be considered for a combined approach.

**Tillage** – Russian olive is sensitive to repeated tillage, especially its seedlings and saplings. This approach is only practical in agronomic situations and should be done in coordination with reseeding and pasture renovation. Disks and plows effectively sever shallow roots. Root sprouting may occur after the first tillage operation so this practice usually has to be repeated. By using tillage in concert with broadleaf weed control spraying, Russian olive saplings may be effectively control.

**Large-scale clearing** – In areas that are densely infested with Russian olive, consider removing trunks and stems in the winter with heavy machinery (such as an excavator). Pulled material should be immediately destroyed by shredding or else piled for later burning. This method is efficient at removing top growth and most root material. However, sprouting often occurs from root parts that remain in the soil (especially from lateral roots). Therefore, consider this approach as being more effective when combined with followup chemical control.

**Prescribed Fire**

Burning will modestly control saplings and can reduce top growth of larger, more mature Russian olive. Since trees will vigorously resprout at a later time after burning, prescribed fire should always be considered to be a suppression technique rather than as a method for eradication. Spring and winter burns are usually less effective than summer or early fall burns.

**Debris Management**

Russian olive can develop new roots from adventitious buds that come in contact with the soil so it is important to remove as much of the plant material as possible. All root and stem remnants should be removed or piled and then destroyed by using fire, shredding, or mulching.

**Cultural Control**

Prevention, early detection, and plant removal are critical for limiting Russian olive establishment. Vehicles, humans, and livestock should be discouraged from traveling through infested areas. Wherever feasible, a program to check and remove seed from vehicles and livestock after travel through infested areas should be implemented to help stop spread. To prevent seed from being transported by irrigation canals, use weed screens on irrigation water intakes inside infested areas if possible.

**Biological Control**

**Grazing**

Mature, trained goats will selectively graze Russian olive seedlings and young trees. A short-term, prescribed grazing approach with goats may not completely eradicate Russian olive but could be one component in a successful management strategy.
**Classical Biological Control**

Research is currently being done to identify biological control agents for Russian olive; however, none of these agents are currently approved for release at this time.

**Chemical Control**

Herbicide control—used either alone or in combination with another method—has been applied with varying success on Russian olive. Sites planned for spraying should be closely evaluated in advance before proceeding with a herbicide control program. Choice of which herbicide to use and the best method of application are influenced by many factors including the time of year to be sprayed, plant growth form (i.e., a low growing, multistemmed shrub versus a mid-sized, single-stem tree), site accessibly, and other considerations. The density of the Russian olive population and the proximity of invasive trees or shrubs to desirable plants further complicates how best to proceed with herbicide control. Herbicide spraying is rarely successful as a one-time treatment, so it is important to anticipate that sites will need to be monitored for several years and new resprouts and seedlings will require further treatment in the future.

Herbicides may be applied by a number of methods including backpack sprayers, ATV or UTV sprayers, boom sprayers that are pulled or attached to a tractor or truck, and

by aerial spraying with a helicopter or fixed-wing aircraft. Treatment options include foliar application, basal bark, and cut-surface methods, which are described in greater detail below. Most compounds available for Russian olive control have postemergent activity and provide limited preemergent control (see herbicide recommendations in table 2.). Each herbicide product will have different requirements and restrictions according to the label. Read and understand prior to any application. Consult the registrant if you have questions or need further detail.

**Foliar Treatment Methods**

**IPT or foliar spot spraying** may be used to control seedlings, saplings, and mature Russian olive that are generally less than 6 feet in height. The practicality of using this approach is influenced primarily by the density and access to the trees to be sprayed. Care needs to be taken to direct spraying so that desirable nearby, nontarget plants are not harmed. When mixing the herbicide solution, consult the label on the need to add a nonionic surfactant (usually 0.25 percent by volume is added). Also, adding a blue indicator dye (0.5 percent) to the mixture is recommended to help view coverage on sprayed plants. Thoroughly wet all green leaves and shoots, especially near the top of the shrub or tree. Plants should be wetted without allowing dripping to occur.

¹Trade names for products are provided for example purposes only, and other products with the same active ingredient(s) may be available. Individual product labels should be examined for specific information and appropriate use with Russian olive.

²Herbicide/water ratio - As an example, a gallon of spray water with a 3 percent mixture is made by adding a sufficient volume of water to 4 ounces of herbicide until a volume of 1 gallon is reached (4 oz ÷ 128 oz/gal = 0.03 or 3 percent).

³2,4-D is a restricted use pesticide in New Mexico only. A certified applicator’s license is required for purchase and use.
Resprouts are common after Russian olive top growth has been removed by operations that involve cutting, tillage, extracting, or shredding; spot spraying is an effective way to control new or returning plants. Wait until plants are about 3 feet tall and have sufficient foliage to allow uptake of herbicide. This may be a year or two after original trees were removed. One successful way for treating resprouts across a large area is to use a team approach whereby each member equipped with a backpack sprayer walks side-by-side about 10 feet apart and sprays plants within their zone. Treated areas should be revisited after 2 or 3 years to respray surviving or missed plants. A 5 percent v/v solution mix using Roundup early in the season, or a mixture of Milestone plus Garlon 4 or imazapyr used later in the season as described in table 2 are effective herbicide treatments.

**Airplane or helicopter applications** can be used to spray mature Russian olive in selected situations. Aerial spraying is usually most practical on mature Russian olive growing in dense, nearly monotypic stands. The aircraft used should be equipped with a satellite guidance system and an onboard GIS display system for spraying in wildland situations. Areas to be sprayed should be premapped and the onboard computer spray system should be preprogrammed to apply herbicide only on defined treatment areas. Helicopters can spray difficult, “tight” areas that require precision application such as edges of meandering rivers or Russian olive stands interspersed with nontarget vegetation. Fixed-wing aircraft are better for spraying large, monotypic blocks of Russian olive where an overlapping spray pattern can be delivered at a lower operational cost than by a helicopter.

Herbicides available for aerial application will defoliate and suppress Russian olive but complete control is rare. Anticipate that followup treatments, such as mechanical control, may be needed in later years. When aerially spraying large trees, the spray volume should be sufficiently high to insure maximum spray coverage. Spray nozzles should be fitted to deliver moderate to large-sized droplets ranging from 450 to 1,200 μm. As indicated in table 2, a spray mixture may include 2 quarts of imazapyr or a 1.5 quart imazapyr plus 1.5 quart glyphosate mixture applied in water. A nonionic surfactant (0.25 percent by volume) and a drift control agent (0.07 percent by volume) should be added to the mixture. For optimum plant control, an aerial application should leave the entire Russian olive canopy glistening with spray liquid long after spraying has occurred.

**Bark Treatment Method**

**IPT basal bark treatments** are most effective on Russian olive that has a stem diameter of 5 inches or less. Apply a solution of 25 to 50 percent triclopyr combined with carrier oil using a low volume, hand-held sprayer fitted with an adjustable nozzle (X0 to X1 orifice size) to deliver a mist spray. Spray around the entire circumference of the stem between ground level and 12 to 15 inches up the stem until bark is wet but not running off. The basal bark method can be used any time of year but is often done in winter when surrounding plants are dormant and impacts to nontarget plant species can be minimized. Adding a dye to the chemical solution will aid in determining continuous and adequate coverage. Leave treated trees in place following spraying.

**Combined Cut-Surface Methods**

There are several different cut-surface methods that can be used to treat Russian olive especially when it is interspersed with sensitive, nontarget plants. These include:

**Cut-stump with herbicide** – This method allows specific trees to be immediately removed and can be used any time of year except under freezing
conditions. Cut the trunk as close to the ground as possible and apply the herbicide solution to the cut surface using a paint brush, wick applicator, or a low volume hand-held or backpack sprayer. The cut surface should be horizontal to the ground to minimize runoff, and any residual sawdust over the cut surface should be removed prior to herbicide application. A solution of triclopyr ester or imazapyr mixed with bark or crop oil must be immediately applied within 15 minutes. The herbicide:oil mixture ratio can vary from 33:67 to 50:50 v/v depending on the number and size of plants to be treated and the application technique used. Lower ratios (e.g., 33:67) are typically used when applications are made with a low volume backpack sprayer or hand-held spray bottle, whereas higher ratios (e.g., 50:50) are used when the solution is brushed directly onto the cut stump. Cut surfaces of plants with less than 4 inches diameter must be thoroughly wetted with herbicide to kill the roots; however, the herbicide should be applied to the cambial layer just inside the bark ring if the diameter of the Russian olive stump exceeds 4 inches. A blue indicator dye should be added to the spray mixture to show prior treatment of stumps. Disposal of trunks, limbs, and other top growth should follow acceptable practices (e.g., stack piles or mulch debris).

**Girdling with herbicide** – Use an ax, saw or chain saw to make two horizontal cuts through the bark and cambial tissue around the entire trunk; cuts should be 3 to 4 inches apart. Using a blunt object (such as the ax head), knock off the bark between the cuts. Spray or paint the cut surface of the girdled area with a 50 to 100 percent concentration of chemical herbicide (such as imazapyr or triclopyr) until the cut surface is thoroughly wet. During the summer, the most effective time to girdle and apply chemical treatment is when Russian olive is fully leafed out and actively growing. Leave tree in place for 2 to 3 years following treatment.

**Injection (hack-and-squirt)** – This method is not recommended for trees with trunk diameters less than 2 inches. A number of specialized tools are available for this method, including the Hypo-hatchet® and tree injector. However, a simple hatchet and quart-sized spray bottle can also be used. Make a circle of unconnected, nonoverlapping, downward-angled cuts (each cut 2 inches wide) into the sapwood; allow 1 to 2 inches of uncut bark between each cut. On average, there will be one hack/cut per each inch of diameter plus one extra cut. Place a small amount of herbicide in each cut as it is made. Each herbicide label will specify the exact quantity of chemical to use within each cut. Generally, 1 to 2 squirts from a quart or pint trigger spray bottle will be equivalent to 1 to 2 milliliters (1/4–1/2 teaspoon). Apply herbicide so cut is wet, but herbicide is not running out. Triclopyr, imazapyr, glyphosate, and 2,4-D with picloram can be used for injection methods.

**Frilling with herbicide** – Similar in approach to hack-and-squirt; however, cuts are connected and slightly overlapping with the bark still attached at the base of the cut to make a frill.

**Control Strategies**

Strategies used for Russian olive control and site restoration must involve careful planning. Numerous research and practical integrated approaches—each with varying success—have been developed to manage Russian olive. Successful long-term management programs (typically more than 5 years) usually include a combination of mechanical, fire, and chemical control methods. A combination of methods is particularly necessary if the primary objective is to achieve long-term stability of native plants. The following strategy is an example of an approach that could be used to contain and reduce populations of Russian olive:

**General combined strategy** – In late fall or winter, use a chain saw to cut Russian olive with stem diameters of 4 inches or greater and then remove the
debris. Within 5 minutes of cutting each tree, apply triclopyr to the cut surface. For stems < 8 inches in diameter, use a 50 percent solution with carrier oil. For stems > 8 inches in diameter, use a 75 to 100 percent solution. Gather and pile dead debris and burn material under safe conditions. After large trees have been removed, evaluate the need to mulch the area by using a mobile, high horsepower tractor that operates a high-speed, rotating drum equipped with cutting teeth. As an alternative, a tractor equipped with a flail-type mower attachment can be used to mow smaller diameter stems and debris that remain. Monitor the area closely to determine the best followup strategy for control. In situations where the return of Russian olive resprouts is low or moderate, a team approach to foliar spray regrowth may be effective. With this approach, members equipped with backpack sprayers move through an area and spot treat seedlings and resprouts for at least 3 consecutive years. Followup treatment options may include spraying with 5 percent glyphosate solution in early summer or a 1 percent imazapyr or aminopyralid + triclopyr mixture later in the season. Continue to monitor for regrowth in later years and hand treat as necessary. In certain areas, goats can be used for a limited time during the spring in a controlled intensive grazing approach on seedlings and resprouts. Fencing may be necessary to confine goats to areas of infestation. Another followup option is to perform a prescribed burn on regrowth using a high heat fire in the late summer to early fall. Monitor for return of Russian olive and spot spray new plants.

Regardless of the initial strategy used, the key to long term Russian olive control is to plan and conduct followup treatments on resprouts and seedlings. Once Russian olive has been removed, aggressive revegetation is often required. Without special planning and care, treated areas may be rapidly reinvaded by Russian olive or other invasive species. Always consider the possible need for seeding or replanting desirable plants before initiating any Russian olive control activities. Managers should understand the revegetation requirements of a site after Russian olive treatment, and include restoration as part of a control strategy. Sustainable control over the long term is best accomplished by planting competitive native plants that have a high exclusionary capability.

**Adaptive Management**

It is important to establish realistic goals and objectives in managing Russian olive, especially when infestations of the tree occur widely across a given landscape. To improve long-term success, consider using an adaptive management strategy with the overall goal of restoring desirable plant communities. The stepwise process for adaptive management involves:

1. Assessment of the overall weed problem,
2. Establishing management goals and objectives,
3. Implementation of control strategies,
4. Monitoring the effectiveness of management actions,
5. Evaluating actual outcomes in relation to expected results, and
6. Adjusting practices as necessary.

Steps of this process should be repeated in sequence as part of a continuous learning cycle that improves management planning and strategy by learning from the outcomes of previous management actions. In general, an adaptive management strategy may be considered to be successful if:

1. Stakeholders are actively involved and remain committed to the process,
2. Monitoring and assessment are used to adjust and improve management decisions, and
3. Management goals and/or objectives for the resource are being achieved.
